

WESTCARB Regional Partnership

Understanding and Managing the Potential for Induced Seismicity in CO₂ Storage Projects

Larry Myer, Imyerco2@gmail.com

Lawrence Berkeley National Laboratory
(Retired)

WESTCARB Annual Business Meeting
Bakersfield, CA

October 15–17, 2012

Outline

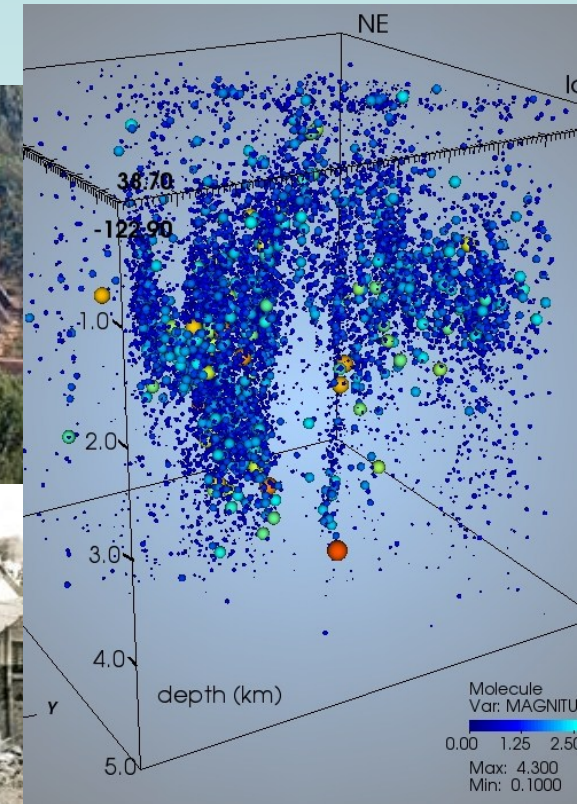

- Introduction
- Some observations, general characteristics of induced seismicity
- Managing the risks of induced seismicity
- Some remaining questions
- Summary

Induced Seismicity is Common in Subsurface Activities

- Seismicity has been associated with reservoir impoundment, mining, fluid injection
- Characteristically many more small events than large ones; once in awhile a large one has occurred.
- Seismicity not all bad – useful for imaging subsurface

Koyana reservoir dam, India, (above) and damage from 1967 M6.5 earthquake (below) (www.indianetzone.com and www.timescontent.com)

Seismicity at Geysers geothermal area (courtesy E Majer, LBNL)

Causal Mechanisms

- Earthquakes (fault slip) occur when the shear stress along a fault is greater than the strength of the fault.
- Induced or triggered earthquakes occur when human activity causes changes in stresses within the Earth that are sufficient to produce slip.
- This can result from:
 - An increase in shear stress along the fault
 - A decrease in strength of the fault
 - Decrease the normal stress across the fault
 - Increase the pore pressure within the fault
 - Decrease in cohesion on fault
 - Thermal stresses

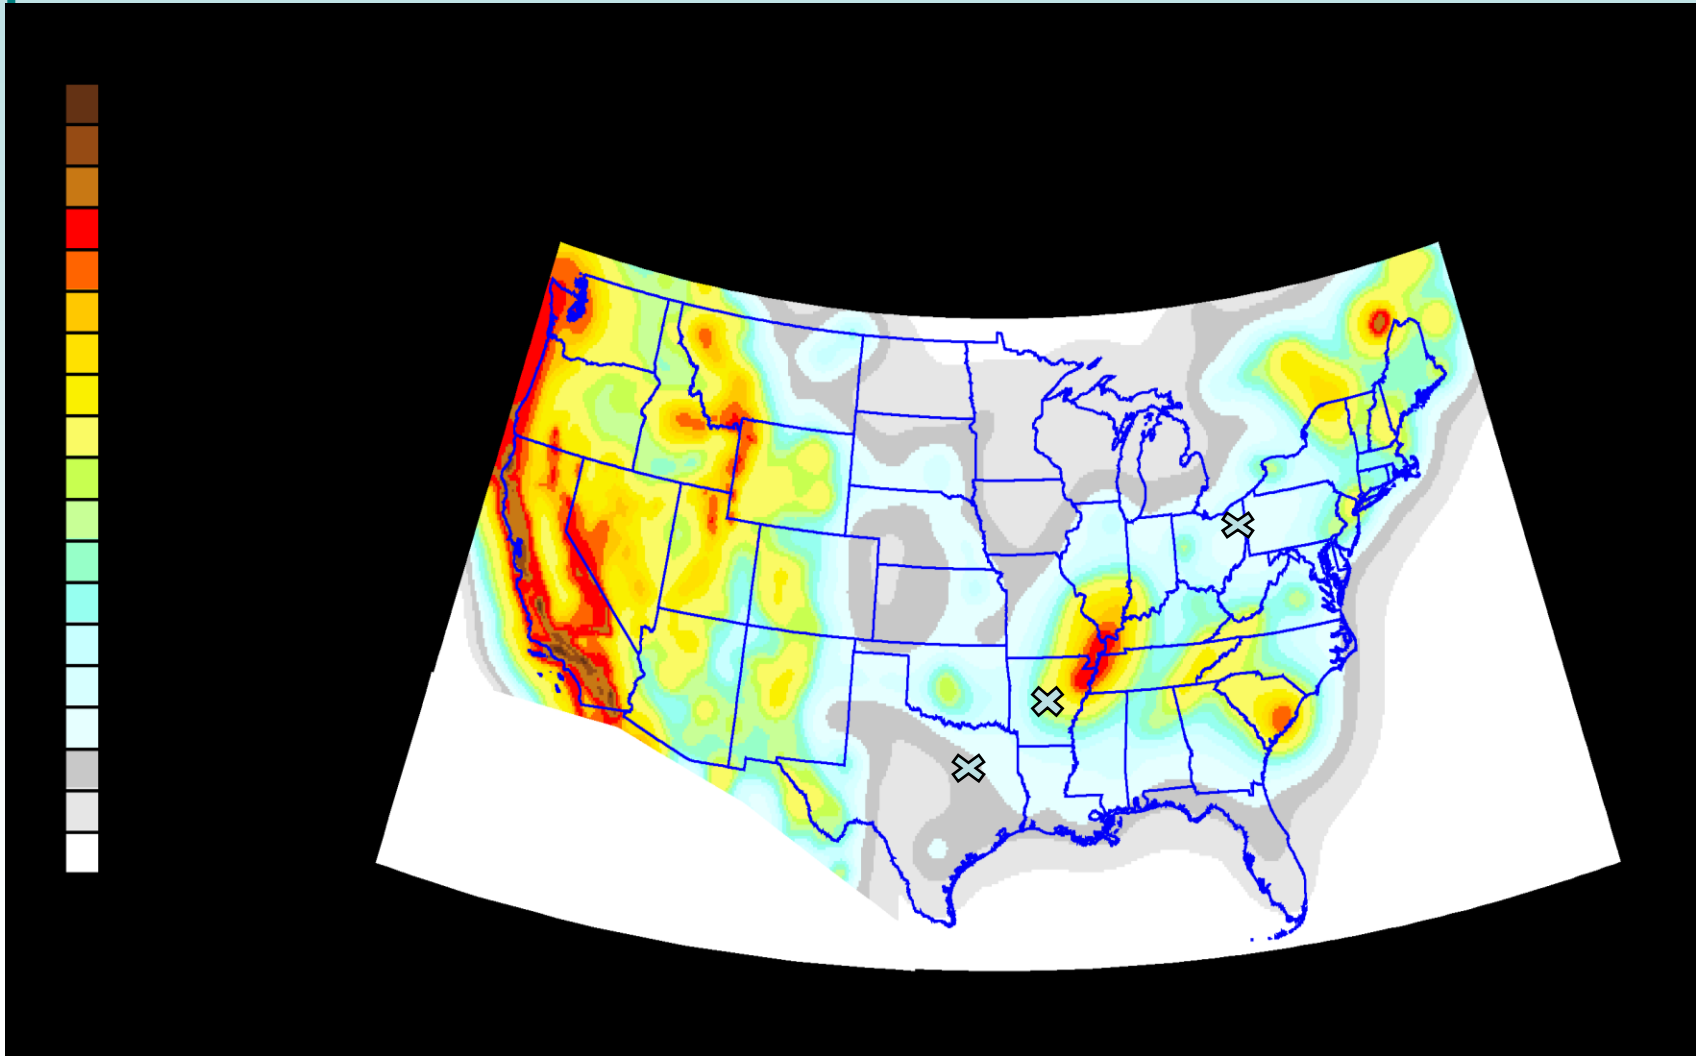

Historical Data: “Felt-Earthquakes” “Likely” Related to Energy Technologies in US

Energy technology	Number of Projects	Number of Felt Induced Events	Maximum Magnitude of Felt Events	Number of Events $M \geq 4.0^d$	Net Reservoir Pressure Change	Mechanism for Induced Seismicity	Location of $M \geq 2.0$ Events
Vapor-dominated geothermal	1	300-400 per year since 2005	4.6	1 to 3 per year	Attempt to maintain balance	Temperature change between injectate and reservoir	CA (The Geysers)
Liquid-dominated geothermal	23	10-40 per year	4.1 ^b	Possibly one	Attempt to maintain balance	Pore pressure increase	CA
Enhanced geothermal systems	~8 pilot projects	2-10 per year	2.6	0	Attempt to maintain balance	Pore pressure increase and cooling	CA, NV
Secondary oil and gas recovery (waterflooding)	~108,000 (wells)	One or more events at 18 sites across the country	4.9	3	Attempt to maintain balance	Pore pressure increase	AL, CA, CO, MS, OK, TX
Tertiary oil and gas recovery (EOR)	~13,000	None known	None known	0	Attempt to maintain balance	Pore pressure increase (likely mechanism)	None known
Hydraulic fracturing for shale gas production	35,000 wells total	1	2.8	0	Initial positive; then withdraw	Pore pressure increase	OK
Hydrocarbon withdrawal	~6,000 fields	20 sites	6.5	5	Withdrawal	Pore pressure decrease	CA, IL, NB, OK, TX
Waste water disposal wells	~30,000	8	4.8 ^c	7	Addition	Pore pressure increase	AR, CO, OH
Carbon capture and storage, small scale	1	None known	None known	0	Addition	Pore pressure increase	IL
Carbon capture and storage, large scale	0	None	None	0	Addition	Pore pressure increase	None yet in operation

Induced Seismicity Not Always in Tectonically Active Areas

✕ Approximate location of recent induced seismicity associated with natural gas development activities

Induced Seismicity Commonly Occurs on Pre-existing Faults

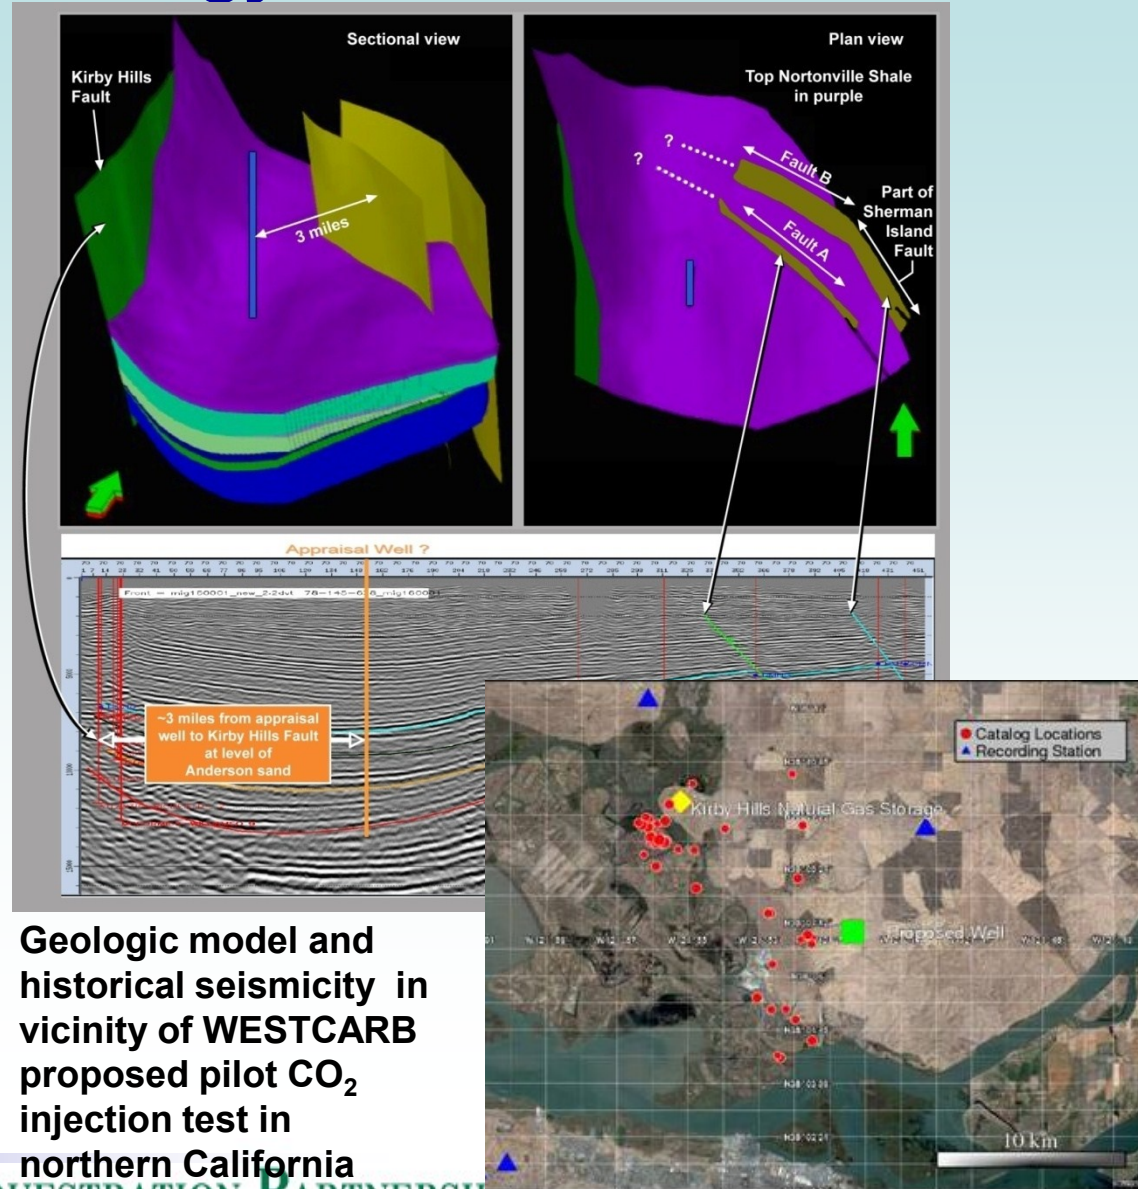

Induced seismicity on Guy-Greenbrier fault, due to fluid Injection activities (maximum event M4.7). (S. Horton, U. Memphis)

The Potential for Induced Seismicity Can Be Managed Using Best Practice Approaches

- Site selection and characterization
- Risk assessment
- Managing reservoir pressures during operation
- Monitoring
- Public outreach
- Event response procedures

Site Characterization Provides Essential Data on Geology, Hydrology, etc

- Develop 3-D geologic model
 - Identify faults
- Determine in-situ stress state
- Determine in-situ fluid pressures; regional hydrologic boundary conditions
- Review historical seismicity – magnitude, location, frequency
- Perform social characterization

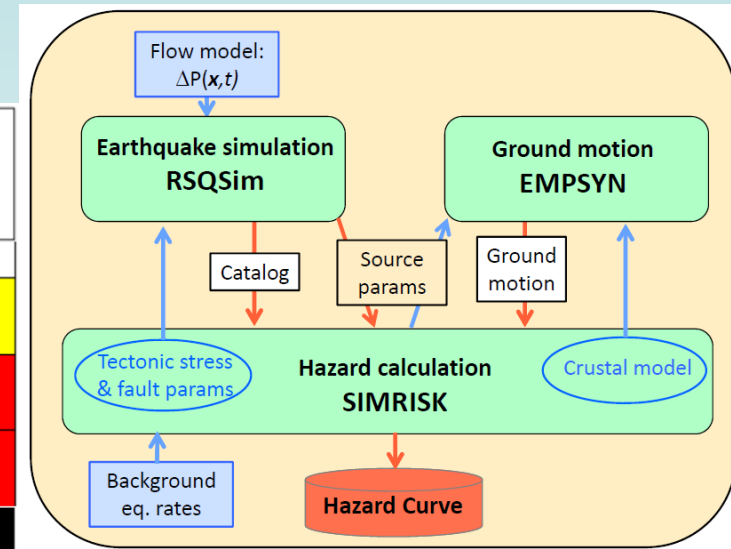

Identify and Analyze Risks, Develop and Implement Risk Response

- Project risk assessment includes induced seismicity along with other potential risks
- Review, consider update of natural seismic hazard assessment of site
- Consider induced seismicity probabilistic hazard analysis

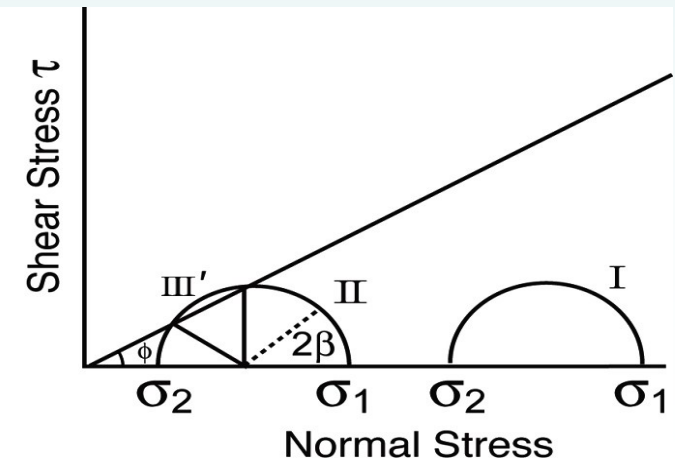

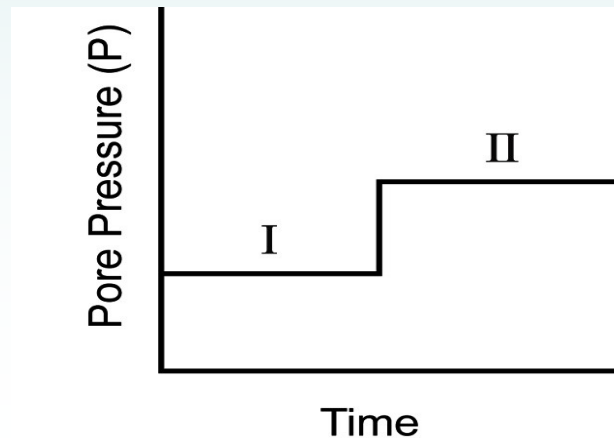

MITIGATION Control Measures		LIKELIHOOD				
		Very Unlikely	Unlikely	Medium Likelihood	Likely	Very Likely
Light	-1	-1 1L	X	X	-4 4L	X
Serious	-2	X	-4 1S	6	X	-10 5S
Major	-3	X	-6 2M	-9 3M	-12 4M	-15 5M
Severe	-4	-4 1C	-8 2C	X	-16 4C	-20 5C
Extreme	-5	X	-10 2MC	-15 3MC	-20 4MC	-25 5MC

White arrow indicates decreasing risk

Managing Reservoir Pressures: Determine Max Allowable Pressure on Faults

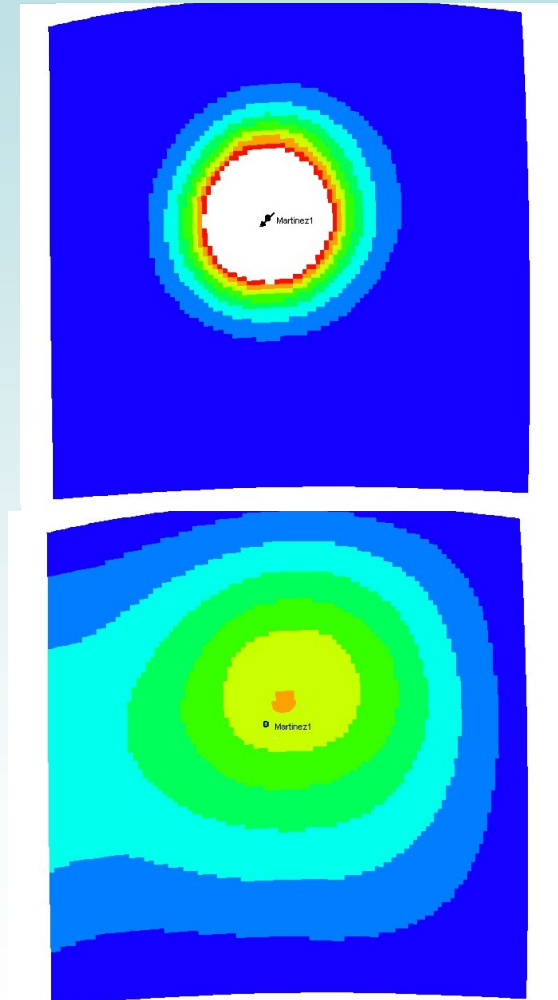

- “Coulomb criterion”: faults slip when frictional resistance (allowable shear stress) is exceeded
- Input data: in-situ stress state and coefficient of friction, μ , of fault
- Determine P , the maximum allowable fluid pressure on fault

Use of “Mohr circles” to evaluate potential for fault slip

Managing Reservoir Pressures: Design of Injection Operations

- Model reservoir pressures – operational period and post-injection
 - Incorporate actual hydrologic boundary conditions
- Consider pressure limits in location and number of injection wells
 - Site injection wells far from faults
- For depleted oil and gas reservoirs, consider setting original reservoir pressure as a limit
- Consider brine extraction for pressure management

Pressure increase around an injection well (blue is zero); top- end of injection; bottom-150 days later; fault on left

Monitoring for Induced Seismicity

- Reservoir pore pressures
 - Direct measurements
 - Indirect: surface displacements, seismic
- Microseismic measurements
 - Permanent sensors; integrate with regional network
 - Integrated with overall seismic monitoring scheme
 - One year or 6 month baseline
- Monitoring need follow from risk assessment – technical risks and social attitudes

Schematic of wells and wellbore monitoring at Decatur RCSP project

Incorporating Induced Seismicity into Public Outreach Programs

- Characterize local attitudes toward seismicity
- Incorporate discussion of seismicity, natural and induced, into project outreach plan
 - Account for technical risk and local attitudes
- Consider making seismic data available to public in “real time”
- Plan ahead for complaints

Purpose
 This informational meeting is being held to discuss plans for a research project to test “carbon sequestration,” a promising new technology that can keep carbon dioxide (CO₂) away from the atmosphere to curb global warming. Also known as CO₂ storage, carbon sequestration involves injecting CO₂ about 1/2 mile underground into porous geologic formations suitable for secure long-term storage. In Arizona, well-scaled, deep-lying formations such as limestone, mudstone, and sandstone are excellent candidates for CO₂ storage. The depth and high salinity of the water in these formations rule out the practicality of using it for human consumption or agriculture. The proposed CO₂ storage test in northeast Arizona will inject a small amount of commercial-grade CO₂ into a dedicated well equipped with sensitive monitoring instrumentation. This will allow researchers to “see” the CO₂ as it is absorbed into the porous rocks. Successful subsurface geologic tests would help confirm the feasibility of ultimately storing CO₂ captured from nearby power plants, which could be required by future regulations.

Everyone is welcome to attend the meeting to learn and ask questions about our proposed project. [Please see our Q & A section on the back of this announcement.]

Drilling Activity for August 1-2, 2009
 Well: APS Cholla Pilot Test Well Rig: WDC Rig 161
 Activity: Drilling
 Drilling progressed from 72 ft to 146 ft. An inclination survey was conducted (1.6 deg at 146 ft). Drilling progressed from 146 ft to 195 ft.

Observations

- Daily activities summarized to 6:00 am.
- Drilling measurements are referenced from Kelly bushing (KB) of Bercat drilling rig (12 ft above GL).
- Conductor pipe: 14" OD, set at 67 ft KB.
- Drilling Mud loggers indicate 10% anhydrite, 40% shale, 50% sand (Moenkopi formation).
- Minimal water losses to formation.

Drilling Activity for August 1-2, 2009
 Well: APS Cholla Pilot CO2 Test Well Rig: WDC Rig 161
 Activity: Drilling
 Drilling progressed from 195 ft to 264 ft at average rate of penetration (ROP) of 6 ft/hr. Top of Cocconino formation was picked by mud logger at 205 ft. An inclination survey was conducted at 264 ft (0 degree hole angle). Drilling progressed from 264 ft to 372 ft at average ROP of 2.2 ft/hr.

Observations

- Daily activities summarized to 6:00 am.
- Drilling measurements are referenced from Kelly bushing (KB) of Bercat drilling rig (12 ft above GL).
- Conductor pipe: 14" OD, set at 47 ft KB
- Mud loggers indicate 100% sand (Cocconino formation).
- Slight water losses to formation.

For an introduction to Geologic Formations [CLICK HERE](#)
 Select a specific formation (below) to learn more about its history and characteristics

Formation	Substrata	Depth (Feet)
Moenkopi Formation	Sandstone/Limestone	0 - 100
Cocconino Sandstone	Sandstone	100 - 800
Supai Formation	Limestone, Mudstone, Halite	1,865 - 1,885
Naco Formation	Siltstone, Mudstone with minor Sandstone/Dolomite	2,525 - 3,075
Martin Formation	Mudstone, Limestone, Sandstone, Dolomite	3,575 - 3,775
Pre-Cambrian Basement	Granite	Below 3,775

Establish Procedures for Responding to Events

- Work with regional authorities to establish protocols
- Set thresholds for a range of actions depending on magnitude of event (where magnitude is tied to shaking potential)
 - Eg., no action if events smaller than M2; suspend injection if $>M4$
 - Take into consideration natural seismicity and location of event
- Consider vibration monitoring of some structures in cultural areas

Some Remaining Questions

Total Seismic Moment May Be Correlated With Injected Volume

McGarr (1976)

$$\sum M_0 = K \cdot \mu \cdot |\Delta V|$$

↑
↑

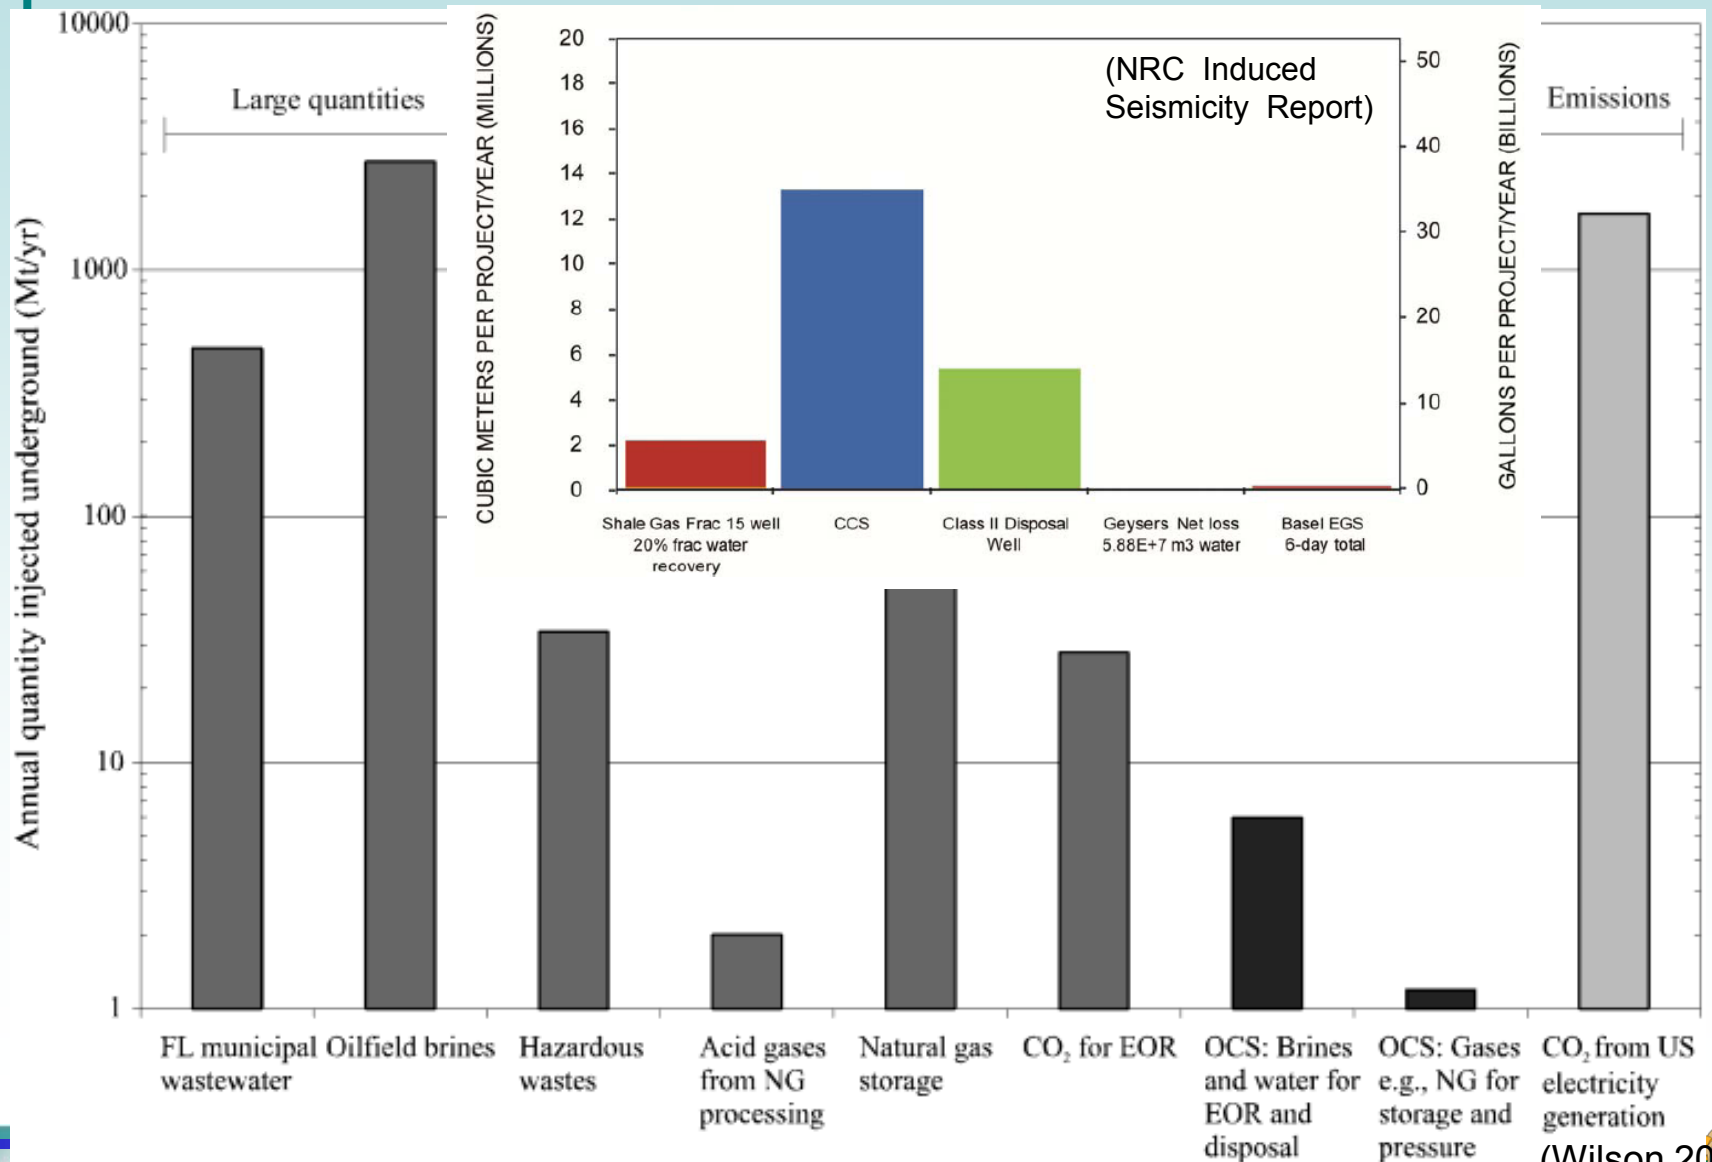

Total Seismic Moment
Fluid injected

→ **K ~ 0.5**

Volume added to region in expansion in direction NW/SE (σ_2) and NE-SW (σ_3)

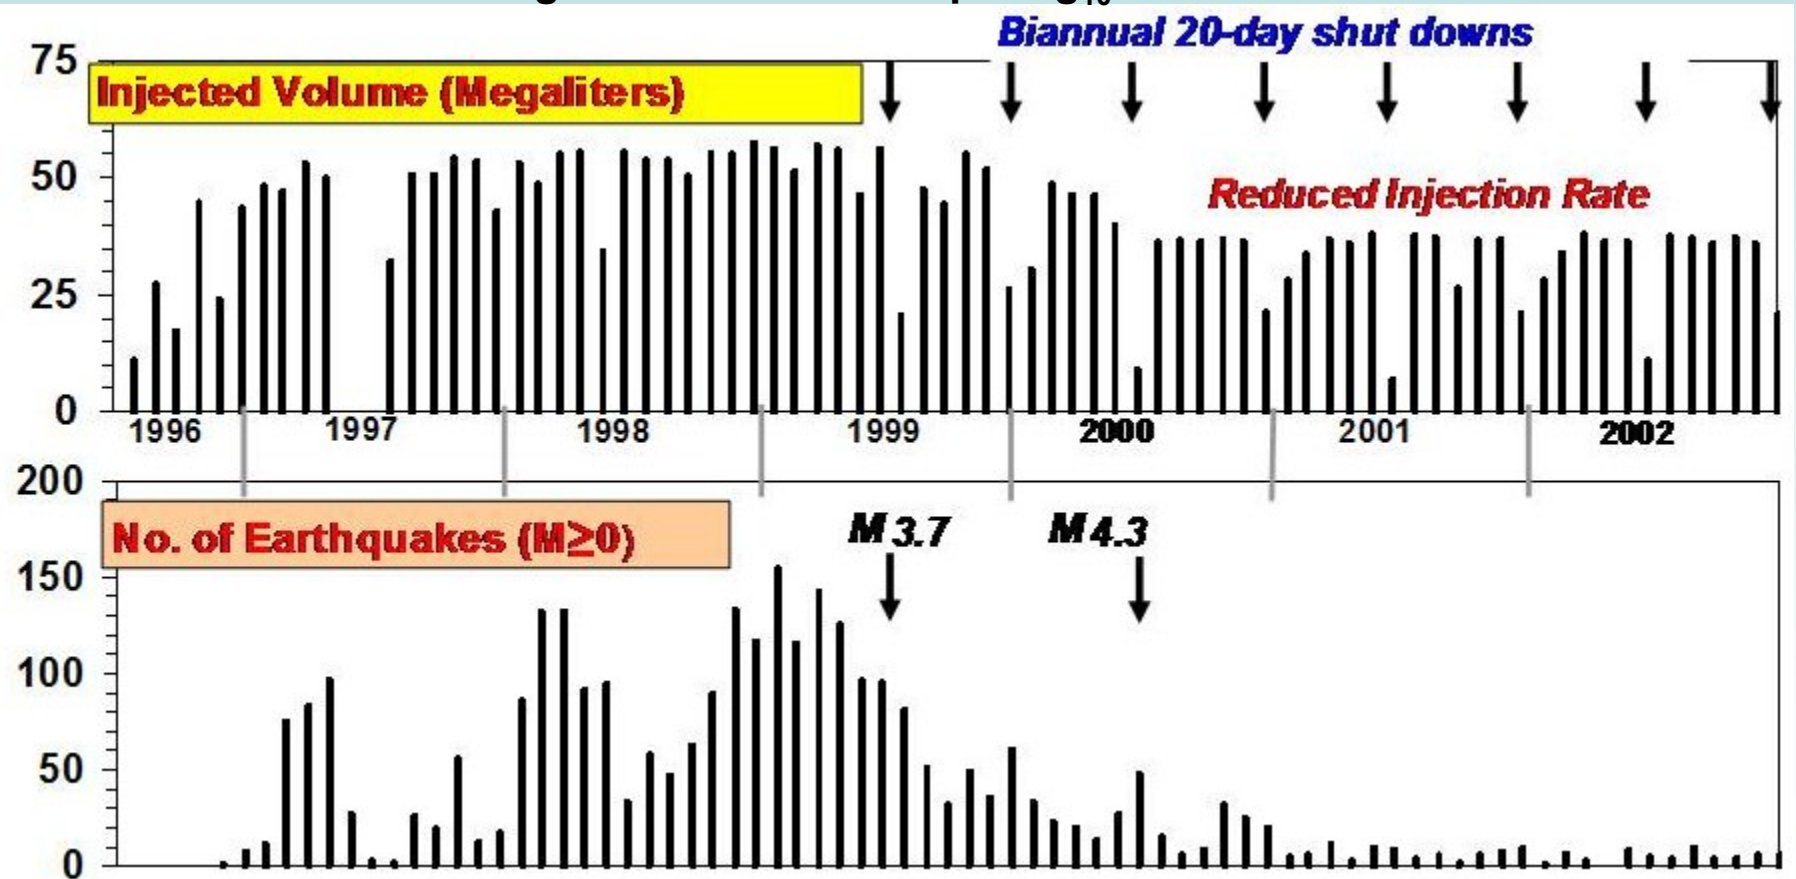

Correlation of total seismic moment and injected volume at Geysers (E Majer, LBNL)

Are Injected CCS Injected Volumes Unprecedented?

“b” Values For Induced and Natural Seismicity May Be Different

Gutenberg-Richter relationship: $\text{Log}_{10} N = a - bM$

Induced seismicity from salt water injection in Paradox Valley, Colorado. “b” values have changed over time. (Ake, US Bureau of Reclamation, NRC)

Summary

- Induced seismicity represents a potential risk for CCS, though it also has potential as a reservoir monitoring tool
 - Very little induced seismicity in CCS projects to date
- Observations indicate induced seismicity very often associated with pre-existing faults, but attributes of induced events may differ from natural seismicity
- Induced seismicity should be addressed as part of the risk assessment carried out for CCS projects; results of risk assessment inform project operations
- The potential for induced seismicity can be managed using best practice approaches in site characterization, monitoring, injection operations and public outreach
